

GitHub Actions Workflow Root Cause Analysis

Issue: Deployment Failure on Self-Hosted Runner

ERROR IDENTIFIED

1. Problem Statement & Logs Analyzed

Your GitHub Actions pipeline failed during the "**Deploying Directly via Self-Hosted Runner**" job. The exact error message from the logs is shown below:

```
cp: cannot create regular file '/home/mr/skillpulse/../../.git/objects/...': Permission denied
Error: Process completed with exit code 1.
```

RCA (Root Cause Analysis): This is not an issue with port mapping or blocking. It is a direct **File Permission / Ownership** conflict. The local user account under which the GitHub Actions runner is executing does not have the necessary privileges to write or modify files within the `/home/mr/skillpulse/` directory or its internal `.git` system folders.

2. Step-by-Step Resolution Guide

To resolve this restriction, you need to log into the specific server/machine where your **Self-Hosted Runner** is active using a terminal or SSH, and execute the following commands:

1. Step 1: Fix Directory Ownership (Recommended)

Assign the ownership of the entire project directory to the specific user running the GitHub runner process. If your runner operates under the user `mr`, execute this command:

```
sudo chown -R mr:mr /home/mr/skillpulse/
```

(Note: If your runner is running under a different user account, replace `mr:mr` with that specific username).

2. Step 2: Grant Directory Write Permissions

If file creation is still blocked due to strict system profiles even after changing ownership, explicitly allow proper read/write/execute permissions:

```
sudo chmod -R 755 /home/mr/skillpulse/
```

3. Step 3: Mark the Git Directory as Safe

Because Git's modern security policies restrict directory mapping across multi-user environments, add this configuration to bypass global ownership checks:

```
git config --global --add safe.directory /home/mr/skillpulse
```

3. Verification

Next Action Step: After running the commands above on your runner machine, return to your GitHub Dashboard, navigate to the failed workflow, and click on **"Re-run jobs"** or **"Re-run failed jobs"**. With the updated file permissions in place, your deployment workflow will execute successfully.
